

# Cl(Cl(4)) = Cl(16) containing E8

Frank Dodd (Tony) Smith, Jr. - 2011

Cl(4) :

1 grade-0: s

4 grade-1: x y z t - M4 physical spacetime

6 grade-2: a b c d e f - M4L Lorentz transformations

4 grade-3: x y z t - CP2 internal symmetry space

1 grade-4: s

Cl(Cl(4)) = Cl(16) for which Physical Interpretations are based on Triality whereby

x y z t x y z t corresponds to

8-dim M4xCP2 Kaluza-Klein SpaceTime

8 elementary Fermion Particles

8 elementary Fermion AntiParticles.

The 8-dim M4xCP2 Kaluza-Klein interpretation is used for Cl(16) grade-1 in which

x y z t x y z t occur as single elements

The 8 Fermion Particle - 8 Fermion AntiParticle

interpretation is used for the gauge forces of grade-2 in which x y z t x y z t occur as antisymmetric pairs.

1 grade-0:

s

16 grade-1:

s

x y z t - M4 physical spacetime

a b c d e f

x y z t - CP2 internal symmetry space

s

Further Physical Interpretations:

Even-Odd Clifford Dual to M4 physical spacetime:

s a b c

Even-Odd Clifford Dual to CP2 internal symmetry space:

d e f s

64-dim to describe 8-dim Kaluza-Klein SpaceTime:

Consider 8-dim K-K as Octonion Spacetime

with Octonion basis  $\{1, i, j, k, E, I, J, K\}$ .

For each of the 8  $x y z t x y z t$  Position dimensions

there are 8 Momentum dimensions represented by

$s a b c s d e f$  and basis elements  $\{1, i, j, k, E, I, J, K\}$ .

The  $a b c$  correspond to an  $SU(2)$  and so to  $\{i, j, k\}$ .

The  $d e f$  correspond to another  $SU(2)$  and to  $\{I, J, K\}$ .

8 s-terms for Real Part of Octonion SpaceTime:

$s_x s_y s_z s_t$

$s_x s_y s_z s_t$

8 s-terms for E-Imaginary Part of Octonion SpaceTime:

$x_s$

$y_s$

$z_s$

$t_s$

$x_s$

$y_s$

$z_s$

$t_s$

24 M4  $ijkIJK$  components of Octonion SpaceTime:

$x_a x_b x_c x_d x_e x_f$

$y_a y_b y_c y_x y_e y_f$

$z_a z_b z_c z_d z_e z_f$

$t_a t_b t_c t_d t_e t_f$

24 CP2  $ijkIJK$  components of Octonion SpaceTime:

$a_x a_y a_z a_t$

$b_x b_y b_z b_t$

$c_x c_y c_z c_t$

$d_x d_y d_z d_t$

$e_x e_y e_z e_t$

$f_x f_y f_z f_t$

E8 is constructed from Cl(16) using grade-2 and half-Spinors so consider Spinors of Real Clifford Algebras:

$M_{16}(\mathbb{R})$	$M_{16}(\mathbb{C})$	$M_{16}(\mathbb{H})$	$M_{16}(\mathbb{H}) \oplus M_{16}(\mathbb{H})$	$M_{32}(\mathbb{H})$	$M_{64}(\mathbb{C})$	$M_{128}(\mathbb{R})$	$M_{128}(\mathbb{R}) \oplus M_{128}(\mathbb{R})$	$M_{256}(\mathbb{R})$

Real Spinors (signatures (2,2) (3,1))

$Cl(4) = M_4(\mathbb{R}) = 4 \times 4$  Real Matrix Algebra

$Cl(8) = M_{16}(\mathbb{R})$  (signature (0,8))

$Cl(16) = M_{16}(\mathbb{R}) \otimes M_{16}(\mathbb{R}) = M_{256}(\mathbb{R})$  (signature (0,16))

Physically, the Real Structures describe  
High-Energy (near Planck scale) Octonionic Physics.

**$Cl(4)$  Spinors:**

4-dim  $x y z t$  space on which  $M_4(\mathbb{R})$  matrices act.

With Spinors defined in terms  
of Even Subalgebra of Clifford Algebra,

$M_4(\mathbb{R})$  reduces to  $M_2(\mathbb{R}) + M_2(\mathbb{R})$

and  $Cl(4)$  Spinors reduce to sum of half-Spinors as  
2-dim  $x y$  space plus 2-dim  $z t$  space.

**$Cl(8)$  Spinors:**

16-dim space on which  $M_{16}(\mathbb{R})$  matrices act.

$M_{16}(\mathbb{R})$  reduces to  $M_8(\mathbb{R}) + M_8(\mathbb{R})$

and  $Cl(8)$  Spinors reduce to sum of half-Spinors as

8-dim  $x y z t x y z t$  +space plus

8-dim  $x y z t x y z t$  -space

where Triality has been used to represent half-Spinors  
in terms of vectors  $x y z t x y z t$  that can be seen  
as  $Cl(4)$  structures.

**$Cl(Cl(4)) = Cl(16)$  Spinors:**

256-dim space on which  $M_{256}(\mathbb{R})$  matrices act.

$M_{256}(\mathbb{R})$  reduces to  $M_{128}(\mathbb{R}) + M_{128}(\mathbb{R})$

and  $Cl(16)$  Spinors  $(8^+ + 8^-) \times (8^+ + 8^-) =$

$= (64^{++} + 64^{--}) + (64^{+-} + 64^{-+}) = 128^{\text{pure}} + 128^{\text{mixed}}$

which reduces to sum of half-Spinors as

128-dim pure space plus 128-dim mixed space.

Only the pure half-Spinor 128-dim space is used to  
construct  $E_8 = 120$ -dim grade-2 + 128-dim half-Spinor.

The pure 128-dim half-Spinor  $64^{++} + 64^{--}$  describes:

8 covariant components of 8 Fermion Particles by  $64^{++}$

8 covariant components of 8 AntiParticles by  $64^{--}$  .

Quaternion Spinors (signatures (0,4) (1,3) (4,0))  
Cl(4) = M2(H) = 2x2 Quaternion Matrix Algebra

Cl(8) = M8(H) (signature (2,6))

Cl(16) = M8(H) (x) M8(H) = M128(H) (signature (4,12))

Physically, Quaternionic Structures describe

Low-Energy (with respect to Planck scale) Physics

which emerges after

Octonion Symmetry is broken

by “freezing out” a preferred Quaternion Substructure

at the End of Inflation

so

Quaternionic Structure is relevant for Low-Energy physics described by Cl(4) and  
observed directly by us now,

but not relevant for Cl(8) or Cl(16) which describe High-Energy physics such as  
that of the Inflationary Era.

**Cl(4) Spinors:**

**8-dim space on which M2(H) matrices act.**

**With Spinors defined in terms**

**of Even Subalgebra of Clifford Algebra,**

**M2(H) reduces to H+H**

**and Cl(4) Spinors reduce to sum of half-Spinors as**

**4-dim space plus 4-dim space**

**which enables Cl(4) to describe Fermion Particles as**

**Lepton + RGB Quarks Particles by one H of H+H plus**

**Lepton + RGB Quarks AntiParticles by the other H of H+H**

**but Cl(4) is not large enough to distinguish Neutrinos**

**from Electrons. To do that it should be expanded into**

**Cl(6) of the Conformal Group (signature (2,4))**

**with Cl(6) = M4(H) and Even Subalgebra M2(H) + M2(H)**

**giving a half-Spinor H+H for 8 Fermion Particles and**

**another half-Spinor H+H for 8 Fermion AntiParticles.**

**In a sense, this expands 4+4=8-dim Batakis Kaluza-Klein**

**to a 6+4=10-dim CNF6 x CP2 Kaluza-Klein,**

**with the M4 Minkowski M4 physical SpaceTime becoming a**

**conformal CNF6 physical SpaceTime**

**that is related to Segal Conformal Dark Energy.**

Higher grades of  $Cl(16)$  are:

**1 grade-16:**

## Higgs as Primitive Idempotent:

Clifford Algebra Primitive Idempotents are described by Pertti Lounesto in his book Clifford Algebras and Spinors (Second Edition, LMS 286, Cambridge 2001) in which he said at pages 226-227 and 29:

"... Primitive idempotents and minimal left ideals An orthonormal basis of  $R(p,q)$  induces a basis of  $Cl(p,q)$ , called the standard basis.

Take a non-scalar element  $e_T$ ,  $e_T^2 = 1$ , from the standard basis of  $Cl(p,q)$ .

Set  $e = (1/2)(1 + e_T)$  and  $f = (1/2)(1 - e_T)$ , then  $e + f = 1$  and  $ef = fe = 0$ .

So  $Cl(p,q)$  decomposes into a sum of two left ideals

$Cl(p,q) = Cl(p,q)e + Cl(p,q)f$ , where [ for  $n = p + q$  ]

$\dim Cl(p,q)e = \dim Cl(p,q)f = [\dim] (1/2) Cl(p,q) = 2^{(n-1)}$ .

Furthermore,

if  $\{ e_{T_1}, e_{T_2}, \dots, e_{T_k} \}$  is a set of non-scalar basis elements

such that  $e_{T_i}^2 = 1$  and  $e_{T_i}e_{T_j} = e_{T_j}e_{T_i}$ ,

then letting the signs vary independently in the product

$(1/2)(1 \pm e_{T_1})(1/2)(1 \pm e_{T_2}) \dots (1/2)(1 \pm e_{T_k})$ ,

one obtains  $2^k$  idempotents which are mutually annihilating and sum up to 1.

The Clifford algebra  $Cl(p,q)$  is thus decomposed into a direct sum of  $2^k$  left ideals, and by construction, each left ideal has dimension  $2^{(n-k)}$ .

In this way one obtains a minimal left ideal by forming a maximal product of non-annihilating and commuting idempotents.

The Radon-Hurwitz number  $r_i$  for  $i$  in  $Z$  is given by

$i \quad 0 \ 1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7$

$r_i \ 0 \ 1 \ 2 \ 2 \ 3 \ 3 \ 3 \ 3$

and the recursion formula  $r_{(i+8)} = r_i + 4$ .

For the negative values of  $i$  one may observe that  $r_{(-1)} = -1$

and  $r_{(-i)} = 1 - i + r_{(i+2)}$  for  $i > 1$ .

$r_{-8} = 1 - 8 + r_{10}$

**Theorem.** In the standard basis of  $Cl(p,q)$  there are always

$k = q - r(q-p)$  non-scalar elements  $e_{T_i}$ ,  $e_{T_i}^2 = 1$ ,

which commute,  $e_{T_i}e_{T_j} = e_{T_j}e_{T_i}$ ,

and generate a group of order  $2^k$ .

The product of the corresponding mutually non-annihilating idempotents,

$f = (1/2)(1 \pm e_{T_1})(1/2)(1 \pm e_{T_2}) \dots (1/2)(1 \pm e_{T_k})$ ,

is primitive in  $Cl(p,q)$ .

Thus, the left ideal  $S = Cl(p,q) f$  is minimal in  $Cl(p,q)$ .

Example ... In the case of  $R(0,7)$  we have  $k = 7 - r_7 = 4$ . Therefore the idempotent  $f = (1/2)(1 + e_{124}) (1/2)(1 + e_{235}) (1/2)(1 + e_{346}) (1/2)(1 + e_{457})$  is primitive to  $Cl(0,7) = 2^{Mat}(8,R)$ . ...”.

Further example of  $R(0,8)$  is discussed by Pertti Lounesto in his book “Spinor Valued Regular Functions in Hypercomplex Analysis” (Report-HTKKMAT-A154 (1979) Helsinki University of Technology) said [in the quote below I have changed his notation for a Clifford algebra from  $R_{(p,q)}$  to  $Cl(p,q)$ ] at pages 40-42:

“... To fix a minimal left ideal  $V$  of  $Cl(p,q)$

we can choose a primitive idempotent  $f$  of  $Cl(p,q)$  so that  $V = Cl(p,q) f$ .

By means of an orthonormal basis  $\{e_1, e_2, \dots, e_n\}$

for [the grade-1 vector part of  $Cl(p,q)$ ]  $Cl^1(p,q)$  we can construct a primitive idempotent  $f$  as follows:

Recall that the  $2^n$  elements

$$e_A = e_{a_1} e_{a_2} \dots e_{a_k},$$

$$1 < a_1 < a_2 < \dots < a_k < n$$

constitute a basis for  $Cl(p,q)$ . ...

$\dim_R V = 2^X$ , where  $X = h$  or  $X = h + 1$  according as

$p - q = 0, 1, 2 \pmod 8$  or  $p - q = 3, 4, 5, 6, 7 \pmod 8$  and  $h = \lfloor n/2 \rfloor$ .

Select  $n - X$  elements  $e_A, e_A^2 = 1$ , so they are pairwise commuting and generate a group of order  $2^{(n - X)}$ .

Then the idempotent ...

$$f = (1/2)(1 + e_{A_1}) (1/2)(1 + e_{A_2}) \dots (1/2)(1 + e_{A_{(n - X)}})$$

is primitive ...

To prove this note that the dimension of  $(1/2)(1 + e_A) Cl(p,q)$  is  $(2^n) / 2$

and so the dimension of  $Cl(p,q) f$  is  $(2^n) / (2^{(n - X)}) = 2^X$ .

Hence,

if there exists such an idempotent  $f$ , then  $f$  is primitive.

To prove that such an idempotent  $f$  exists in every Clifford algebra  $Cl(p,q)$

we may first check the lower dimensional cases and then proceed by making use of the isomorphism  $Cl(p,q) \times Cl(0,8) = Cl(p, q + 8)$

and the fact that  $Cl(0,8)$  has a primitive idempotent

$$f = (1/2)(1 + e_{1248}) (1/2)(1 + e_{2358}) (1/2)(1 + e_{3468}) (1/2)(1 + e_{4578}) \\ = (1/16)(1 + e_{1248} + e_{2358} + e_{3468} + e_{4578} + e_{5618} + e_{6728} + e_{7138} \\ - e_{3567} - e_{4671} - e_{5712} - e_{6123} - e_{7234} - e_{1345} - e_{2456} + e_J)$$

with four factors [and where  $J = 12345678$ ] ...

The division ring  $F = f Cl(p,q) f = \{ \psi \in V \mid \psi f = f \psi \}$

is isomorphic to  $R, C$ , or  $H$

according as  $p - q = 0, 1, 2, \text{ mod } 8$ ,  $p - q = 3 \text{ mod } 4$ , or  $p - q = 4, 5, 6 \text{ mod } 8$ . ...".  
 In "Idempotent Structure of Clifford Algebras" (Acta Applicandae Mathematicae 9 (1987) 165-173) Pertti Lounesto and G. P. Wene said:

"... An idempotent  $e$  is primitive if it is not a sum of two nonzero annihilating idempotents and minimal if it is a minimal element in the set of all nonzero idempotents with order relation  $f \leq e$  if and only if  $ef = f = fe$ .

These last two properties of an idempotent  $e$  are equivalent. An idempotent  $e$  is primitive if  $e$  is the only nonzero idempotent of the subring  $eAe$ .

A subring  $S$  of  $A$  is a left ideal if  $ax$  is in  $S$  for all  $a$  in  $A$  and  $x$  in  $S$ .

A left ideal is minimal if it does not contain properly any nonzero left ideals.

... if  $S$  is a minimal left ideal of  $A$ ,

then either  $Ss = 0$  or  $S = Ae$  for some idempotent  $e$ .

Spinor spaces are minimal left ideals of a Clifford algebra.

Any minimal left ideal  $S$  of a Clifford algebra  $A = R_{p,q}$  is of the form  $S = Ae$  for some primitive idempotent  $e$  of  $R_{p,q}$ .

... if  $e$  is a primitive idempotent of  $R_{p,q}$  then

$$\begin{matrix} e & 0 \\ 0 & 0 \end{matrix}$$

is a primitive idempotent of  $R_{p,q}(2) = R_{p+1,q+1}$

... The maximum number of mutually annihilating primitive idempotents in the Clifford algebra  $R_{p,q}$  is  $2^k$  where  $k = q - r - p$ .

...[where]...  $r$  ...[is the]... Radon-Hurwitz number ...

These mutually annihilating primitive idempotents sum up to 1.

If mutually annihilating primitive idempotents sum up to 1,

then in a simple ring, such a sum has always the same number of summands.

... Lattices Generated by Idempotents

A lattice is a partially ordered set where each subset of two elements has a least upper bound and a greatest lower bound. Any set of idempotents of a ring  $A$  is partially ordered under the ordering defined by  $e \leq f$  if and only if  $ef = e = fe$ .

If  $e$  and  $f$  are commuting idempotents, then  $ef$  and  $e + f - ef$  are, respectively, a greatest lower bound and a least upper bound relative to the partial ordering defined. Hence, any set of commuting idempotents generate a lattice.

This lattice is complemented and distributive.

...

Let  $e_1, e_2, \dots, e_s$  in  $R_{p,q}$  be a set of mutually annihilating primitive idempotents summing up to 1. Then the set  $e_1, e_2, \dots, e_s$  generates a complemented and distributive lattice of order  $2^s$ , where  $s = 2^k$ ,  $k = q - r - p$

...

EXAMPLE [ I have changed the example from  $R_{3,1}$  to  $R_{0,8}$  and paraphrased ]

In the Clifford algebra  $R_{0,8} = R(16)$  we have  $k = 8 - r - p = 8 - 4 = 4$

and so primitive idempotents can have 4 commuting factors of type  $(1/2)(1 + eT)$  .  
 Furthermore  $s = 2^k = 16$  and so  $R_{0,8}$  can be represented by  $16 \times 16$  matrices  $R(16)$ ,  
 and there are  $2^s = 2^{16} = 65,536$  commuting idempotents in the lattice generated  
 by the 16 mutually annihilating primitive idempotents ...  
 this lattice looks like ... a 16-dimensional analogy of the cube ...”.

**The Clifford algebra  $R_{0,8} = Cl(0,8)$  is  $2^8 = 16 \times 16 = 256$ -dimensional with  
 graded structure such that it  
 is represented by the geometric structure of a simplex.**

**The Spinors of  $R_{0,8} = Cl(0,8)$  are  $\sqrt{256} = 16$ -dimensional with no simplex-  
 type graded structure so that it  
 is represented by the geometric structure of a cube.**

**248-dim  $E_8 = 120$ -dim  $Cl(16)$  bivectors + 128-dim  $Cl(16)$  half-spinors and  
 $Cl(16) = Cl(8) \times Cl(8)$   
 so the structure of the 128-dim  $Cl(16)$  half-spinors is important for  $E_8$   
 Physics.**

The Clifford algebra  $Cl(16)$  (also denoted  $R_{0,16}$ ) is the real  $256 \times 256$  matrix  
 algebra  $R(256)$  for which we have  $k = 16 - r_{16} = 16 - 8 = 8$   
 and so primitive idempotents can have 8 commuting factors of type  $(1/2)(1 + eT)$  .  
 Furthermore  $s = 2^k = 256$  and so  $R_{0,16}$  can be represented by  $256 \times 256$  matrices  
 $R(256)$ , and there are  $2^s = 2^{256} = 1.158 \times 10^{77}$  commuting idempotents in the  
 lattice generated by the 256 mutually annihilating primitive idempotents.

**$E_8$  lives in  $Cl(16)$  as**  
**248-dim  $E_8 = 120$ -dim bivectors of  $Cl(16)$  + 128-dim half-spinor of  $Cl(16)$ .**  
 Since  $Cl(16)$  bivectors are all in one grade of  $Cl(16)$   
 and  $Cl(16)$  half-spinors have no simplex-type graded structure  
 $E_8$  does not get detailed graded structure from  $Cl(16)$  gradings,  
 but only the Even-Odd grading obtained by  
 splitting 128-dim half-spinor into two mirror image 64-dim parts:  
 **$E_8 = 64 + 120 + 64$**

**$E_8$  has only a  $Cl(16)$  half-spinor so there are in  $E_8$  Physics  $2^{(s/2)} = 2^{128}$   
 commuting idempotents in the lattice generated by the 128 mutually  
 annihilating primitive idempotents.  $2^{128} = \text{about } 3.4 \times 10^{38}$  the square root  
 of which is about the ratio ( Hadron mass / Planck mass )<sup>2</sup> of the Effective  
 Mass Factor for Gravity strength.**

The typical Hadron mass can be thought of in terms of superposition of Pions:

In E8 Physics, at a single spacetime vertex, a Planck-mass black hole is the Many-Worlds quantum sum of all possible virtual first-generation particle-antiparticle fermion pairs permitted by the Pauli exclusion principle to live on that vertex. Once a Planck-mass black hole is formed, it is stable in E8 Physics. Less mass would not be gravitationally bound at the vertex. More mass at the vertex would decay by Hawking radiation. Since Dirac fermions in 4-dimensional spacetime can be massive (and are massive at low enough energies for the Higgs mechanism to act), the Planck mass in 4-dimensional spacetime is the sum of masses of all possible virtual first-generation particle-antiparticle fermion pairs permitted by the Pauli exclusion principle. A typical combination should have several quarks, several antiquarks, a few colorless quark-antiquark pairs that would be equivalent to pions, and some leptons and antileptons. Due to the Pauli exclusion principle, no fermion lepton or quark could be present at the vertex more than twice unless they are in the form of boson pions, colorless first-generation quark-antiquark pairs not subject to the Pauli exclusion principle. Of the 64 particle-antiparticle pairs, 12 are pions. A typical combination should have about 6 pions.

If all the pions are independent, the typical combination should have a mass of  $0.14 \times 6 \text{ GeV} = 0.84 \text{ GeV}$ . However, just as the pion mass of  $0.14 \text{ GeV}$  is less than the sum of the masses of a quark and an antiquark, pairs of oppositely charged pions may form a bound state of less mass than the sum of two pion masses. If such a bound state of oppositely charged pions has a mass as small as  $0.1 \text{ GeV}$ , and if the typical combination has one such pair and 4 other pions, then the typical combination should have a mass in the range of  $0.66 \text{ GeV}$  so that

$$\begin{aligned} \sqrt{3.4 \times 10^{38}} &= 1.84 \times 10^{19} \\ \text{while Planck Mass} &= 1.22 \times 10^{19} \text{ GeV} = 1.30 \times 10^{19} \text{ Proton Mass} = \\ &= 1.85 \times 10^{19} \text{ Hadron Mass} \end{aligned}$$

**In terms of the Graded Structure of Cl(16)  
the 256 Cl(16) Primitive Idempotents can be understood  
in terms of graded structures of the Cl(8) and E8 substructures of Cl(16):**

**The detailed E8 graded structure  $8 + 28 + 56 + 64 + 56 + 28 + 8$   
comes from the grades of the Cl(8) factors of  $Cl(16) = Cl(8) \times Cl(8)$ .**

**The Even 120 of E8 breaks down in terms of Cl(8) factors as**

$$120 = 1 \times 28 + 8 \times 8 + 28 \times 1 = 28 + 64 + 28$$

**The Odd 128 = 64 + 64 breaks down as**

$$\begin{aligned} \text{Spinors:} & \quad (8s \times 8s + 8c \times 8c) \\ (8s + 8c) \times (8s + 8c) & = \quad + \\ & \quad (8s \times 8c + 8c \times 8s) \end{aligned}$$

**to become**  
 $64 + 64 = 8 + 56 + 56 + 8$

**Here are some details about the half-spinors of E8:**

The **+half-spinors (red)** and **-half-spinors (green)** of  $Cl(8)$  are the  $8+8 = 16$  diagonal entries of the  $16 \times 16$  real matrix algebra that is  $Cl(8)$ , so that  $Cl(16) = Cl(8) \times Cl(8)$  can be represented as:

and the  $16 \times 16 = 256$  spinors of  $Cl(16)$  (the diagonal entries of  $R(256)$ ) can be represented as the sum of the diagonal product terms

$$64+64 = 128$$

(these two (pure red and pure green) are the  $Cl(16)$  +half-spinor which decomposes physically into particles (red) and antiparticles (green))

+

$$64+64 = 128$$

(these two (mixed red and green) are the  $Cl(16)$  -half-spinor which do not decompose readily into particles (red) and antiparticles (green))

**grade-16: 1 PurePI** 

so it is the only half-spinor that can physically represent a Higgs scalar and is the only half-spinor in the E8 of E8 Physics.

Further, for E8 to describe a consistent E8 Physics model, it must be that

E8 = Cl(16) bivectors + Cl(16) +half-spinor  
with physical distinction between particles and antiparticles  
and that

E8 does not contain the Cl(16) -half-spinor made up of particle/antiparticle mixtures.

In the context of physics models, the Cl(16) -half-spinors correspond to fermion antigerations that are not realistic and their omission from E8 allows E8 Physics to be chiral and realistic.

E8 with graded structure  $8 + 28 + 56 + 64 + 56 + 28 + 8$  lives in Cl(16)  
as

$248\text{-dim E8} = 120\text{-dim bivectors of Cl(16)} + 128\text{-dim half-spinor of Cl(16)}$ .

The two half-spinors of Cl(16) are Left Ideals of a Cl(16) Primitive Idempotent.

Due to 8-periodicity of Real Clifford Algebras  $Cl(16) = Cl(8) \times Cl(8)$  where  $\times$  is tensor product. Let Primitive Idempotent be denoted by PI and  $J = 12345678$  :

$$Cl(16)PI = Cl(8)PI \times Cl(8)PI$$

$$Cl(8)PI = (1/16) ( 1 + e_{_1248} ) ( 1 + e_{_2358} ) ( 1 + e_{_3468} ) ( 1 + e_{_4578} ) =$$

$$= (1/16)( 1$$

$$+ e_{_1248} + e_{_2358} + e_{_3468} + e_{_4578} + e_{_5618} + e_{_6728} + e_{_7138}$$

$$- e_{_3567} - e_{_4671} - e_{_5712} - e_{_6123} - e_{_7234} - e_{_1345} - e_{_2456}$$

$$+ e_{_J} ) =$$

$$= (1/16)($$

$$1 +$$

$$+ e_{_1248} + e_{_2358} + e_{_3468}$$

$$- e_{_3567} - e_{_4671} - e_{_5712}$$

$$+ e_{_J}$$

$$+ e_{_4578} + e_{_5618} + e_{_6728} + e_{_7138}$$

$$- e_{_6123} - e_{_7234} - e_{_1345} - e_{_2456}$$

$$)$$

256-dim Cl(8) has graded structure  $1 + 8 + 28 + 56 + 70 + 56 + 28 + 8 + 1$

16-dim Cl(8)PI has graded structure  $1 + 14 + 1 = 1 + (8+6) + 1$

16-dim Cl(8)PI = 8-dim Cl(8)PIE8 + 8-dim Cl(8)PInotE8

where

8-dim Cl(8)PIE8 has graded structure of only 8 in the middle grade

plus

8-dim Cl(8)PInotE8 has graded structure  $1 + 6 + 1$

8-dim Cl(8)PIE8 is contained in the middle 64 of E8 graded structure

$8 + 28 + 56 + 64 + 56 + 28 + 8$

so that

since the physical interpretation of the middle 64 is

8 momentum components of 8-dim position spacetime

the 8-dim Cl(8)PIE8 corresponds to a one-component field over 8-dim spacetime

and

therefore Cl(8)PIE8 describes a scalar field over 8-dim spacetime

and so a Higgs field in E8 Physics spacetime.

8-dim Cl(8)PInotE8 with graded structure  $1 + 6 + 1$

corresponds to the part of Cl(8)PI that is in Cl(8) but not in E8

so that

Cl(8) with graded structure  $1 + 8 + 28 + 56 + 70 + 56 + 28 + 8 + 1$

=

Cl(8)PInotE8 with graded structure  $1 + 6 + 1$

+

E8 with graded structure  $8 + 28 + 56 + 64 + 56 + 28 + 8$

and

therefore Cl(8)PInotE8 describes the Clifford algebra structure beyond E8

(1 scalar and 6 middle-grade and 1 pseudoscalar)

that produces the half-spinors that belong to E8

and

therefore describes the coupling between the Higgs field and half-spinor Fermions.

The Higgs-Fermion coupling, below the freezing out of a preferred Quaternionic substructure of 8-dim Octonionic E8 Physics spacetime, produces the Mayer Mechanism Higgs field of 8-dim Batakis Kaluza-Klein spacetime.

The Higgs-Fermion coupling, below ElectroWeak Symmetry Breaking Energy, gives mass to Fermions.

**Since the 128-dim half-spinor part of E8 comes from  
Cl(16)PI = Cl(8)PI x Cl(8)PI  
the E8 Higgs-Fermion is based on  
two copies (one from each Cl(8)PI factor) of a scalar Higgs field over  
spacetime**

so that

**two copies of Cl(8)PIE8 show that the E8 Physics Higgs field is  
a scalar doublet.**

As Cottingham and Greenwood said in their book “An Introduction to the Standard Model of Particle Physics” (2nd ed, Cambridge 2007):  
“... Higgs ... mechanism ...[uses]... a complex scalar field ... [i]n place of [which]... we [can] have two coupled real scalar fields ...”.

As Steven Weinberg said in his book “The Quantum Theory of Fields, v. II” (Cambridge 1996 at pages 317-318 and 356):  
“... With only a single type of scalar doublet, there is just one ... term that satisfies SU(2) and Lorentz invariance ... At energies below the electroweak breaking scale, this yields an effective interaction ... this gives lepton number non-conserving neutrino masses at most of order  $(300 \text{ GeV})^2 / M$  ... For instance, in the so-called see-saw mechanism, a neutrino mass of this order would be produced by exchange of a heavy neutral lepton of mass  $M$  ...  $M$  is expected to be of order  $10^{15} - 10^{18} \text{ GeV}$ , so we would expect neutrino masses in the range  $10^{-4} - 10^{-1}$  ... A similar analysis shows that there are interactions of dimensionality six that violate both baryon and lepton number conservation, involving three quark fields and one lepton field. Such interactions would have coupling constants of order  $M^{-2}$ , and would lead to processes like proton decay, with rates proportional to  $M^{-4}$ . ...”.

and

the part of the Cl(16) Primitive Idempotent that is not in the E8 in Cl(16) is the product Cl(8)PInotE8 x Cl(8)PInotE8 of two copies of Cl(8)PInotE8 each copy having graded structure 1 + 6 + 1 (grades 0 and 4 and 8) so that

the part of the Cl(16) Primitive Idempotent that is not in the E8 in Cl(16) has graded structure 1 + 12 + 38 + 12 + 1 (grades 0 and 4 and 8 and 12 and 16). The total dimension of those Cl(16) grades are:  
1 and 1820 and 128870 and 1820 and 1.

$$\mathbf{Cl(8)} \quad \mathbf{256 = 1 + 8 + 28 + 56 + 70 + 56 + 28 + 8 + 1}$$

... There is one three-parameter family of triples ...

Only one set of four MU bases exists ...

there is a unique way to a construct five MU bases which is easily seen to be  
 equivalent to the standard construction of a complete set of MU bases ...  $d = 4$  ...

$d$	2	3	4	5	6
pairs	1	1	$\infty^1$	1	$\geq \infty^3$
triples	1	1	$\infty^3$	2	$\geq \infty^2$
quadruples	-	1	1	1	?
quintuples	-	-	1	1	?
sextuples	-	-	-	1	?

... The notion of equivalence used in this paper ... is mathematical in nature ...

Motivated by experiments, there is a finer equivalence of complete sets of MU  
 bases based on the entanglement structure of the states contained in each basis ...

For dimensions that are a power of two, a complete set of MU bases can be  
 realized using Pauli operators acting on each two-dimensional subsystem.

Two sets of MU bases are then called equivalent when they can be factored into the  
 same number of subsystems. For  $d = 2, 4$  this notion of equivalence also leads to a  
 unique set of  $(d + 1)$  MU bases. However, for  $d = 8, 16, \dots$  complete sets of MU  
 bases can have different entanglement structures even though they are equivalent  
 up to an overall unitary transformation ...”.

P. Dita in arXiv 1002.4933 said:

“... Mutually unbiased bases (MUBs) constitute a basic concept of quantum information ... Its origin is in the Schwinger paper ... “Unitary operator bases”, Proc.Nat. Acad. Sci.USA, 46 570-579 (1960) ...

Two orthonormal bases in  $\mathbb{C}^d$ ,  $A = (a_1, \dots, a_d)$  and  $B = (b_1, \dots, b_d)$ , are called MUBs if ... the product  $A B^*$  of the two complex Hadamard matrices generated by  $A$  and  $B$  is again a Hadamard matrix, where  $*$  denotes the Hermitian conjugate ... The technique for getting MUBs for  $p$  prime was given by Schwinger ... who made use of the properties of the Heisenberg-Weyl group

...

[ in this paper ] An analytical method for getting new complex Hadamard matrices by using mutually unbiased bases and a nonlinear doubling formula is provided. The method is illustrated with the  $n = 4$  case that leads to a rich family of eight-dimensional Hadamard matrices that depend on five arbitrary phases ... The ... matrices are new ... the only [ prior ] known result parametrized by five phases is the [  $n = 8$  ] complex Hadamard matrix stemming from the Fourier matrix  $F_8$

...

real Sylvester-Hadamard matrices ...[ have a ]... solution for  $n = 8$  ...

$$S = \begin{bmatrix} a & b & c & d & l & m & n & p \\ b & -a & -d & c & m & -l & p & -n \\ c & d & -a & -b & n & -p & -l & m \\ d & -c & b & -a & p & n & -m & -l \\ l & -m & -n & -p & -a & b & c & d \\ m & l & p & -n & -b & -a & d & -c \\ n & -p & l & m & -c & -d & -a & b \\ p & n & -m & l & -d & c & -b & -a \end{bmatrix}$$

... for real Hadamard matrices with dimension  $d = 2, 4, 8, 12$  there is only one matrix under the usual equivalence ... there is an other type of matrix equivalence ... two matrices ... are equivalent if and only if they have the same spectrum ... However a simple spectral computation of the  $h_1, h_2, h_3, h_4$  matrices shows that only the matrices  $h_1$  and  $h_3$  are equivalent, and  $h_1$  is not equivalent to  $h_2$  and  $h_4$ , nor  $h_2$  is equivalent to  $h_4$  ...[ so that ]... we do not suggest the use of the new equivalence ... for real Hadamard matrices ... because it will cause dramatic changes in the field ...”.

## Standard Model Higgs compared to E8 Physics Higgs

The conventional Standard Model has structure:

spacetime is a base manifold;

particles are representations of gauge groups

gauge bosons are in the adjoint representation

fermions are in other representations (analogous to spinor)

Higgs boson is in scalar representation.

E8 Physics ( see vixra 1108.0027 and tony5m17h.net ) has structure

(from 248-dim E8 = 120-dim adjoint D8 + 128-dim half-spinor D8):

spacetime is in the adjoint D8 part of E8 (64 of 120 D8 adjoints)

gauge bosons are in the adjoint D8 part of E8 (56 of the 120 D8 adjoints)

fermions are in the half-spinor D8 part of E8 (64+64 of the 128 D8 half-spinors).

There is no room for a fundamental Higgs in the E8 of E8 Physics.

However,

for E8 Physics to include the observed results of the Standard Model

it must have something that acts like the Standard Model Higgs

even though it will NOT be a fundamental particle.

To see how the E8 Physics Higgs works,

embed E8 into the 256-dimensional real Clifford algebra Cl(8):

$$\text{Cl}(8) \quad 256 = 1 + 8 + 28 + 56 + 70 + 56 + 28 + 8 + 1$$

$$\text{Primitive} \quad 16 = 1 \quad + 6 \quad + 1$$

$$\text{Idempotent} \quad + 8$$

$$\text{E8 Root Vectors} \quad 240 = 8 + 28 + 56 + 56 + 56 + 28 + 8$$

The Cl(8) Primitive Idempotent is 16-dimensional and can be decomposed into two 8-dimensional half-spinor parts each of which is related by Triality to 8-dimensional spacetime and has Octonionic structure. In that decomposition:

the  $1+6+1 = (1+3)+(3+1)$  is related to two copies of

a 4-dimensional Associative Quaternionic subspace of the Octonionic structure and

the  $8 = 4+4$  is related to two copies of

a 4-dimensional Co-Associative subspace of the Octonionic structure

(see the book "Spinors and Calibrations" by F. Reese Harvey)

The  $8 = 4+4$  Co-Associative part of the  $Cl(8)$  Primitive Idempotent when combined with the 240 E8 Root Vectors forms the full 248-dimensional E8. It represents a Cartan subalgebra of the E8 Lie algebra.

**The  $(1+3)+(3+1)$  Associative part of the  $Cl(8)$  Primitive Idempotent is the Higgs of E8 Physics.**

The half-spinors generated by the E8 Higgs part of the  $Cl(8)$  Primitive Idempotent represent:

neutrino; red, green, blue down quarks; red, green, blue up quarks; electron  
so  
the E8 Higgs effectively creates/annihilates the fundamental fermions and  
**the E8 Higgs is effectively a condensate of fundamental fermions.**

In E8 Physics the high-energy 8-dimensional Octonionic spacetime reduces, by freezing out a preferred 4-dim Associative Quaternionic subspace, to a  $4+4$  -dimensional Batakis Kaluza-Klein of the form  $M4 \times CP2$  with 4-dim  $M4$  physical spacetime.

Since the  $(1+3)+(3+1)$  part of the  $Cl(8)$  Primitive Idempotent includes the  $Cl(8)$  grade-0 scalar 1 and  $3+3 = 6$  of the  $Cl(8)$  grade-4 which act as pseudoscalars for 4-dim spacetime and the  $Cl(8)$  grade-8 pseudoscalar 1

**the E8 Higgs transforms with respect to 4-dim spacetime as a scalar (or pseudoscalar) and in that respect is similar to Standard Model Higgs.**

Not only does the E8 Higgs fermion condensate transform with respect to 4-dim physical spacetime like the Standard Model Higgs but

**the geometry of the reduction from 8-dim Octonionic spacetime to  $4+4$  -dimensional Batakis Kaluza-Klein, by the Mayer mechanism, gives E8 Higgs the ElectroWeak Symmetry-Breaking Ginzburg-Landau structure.**

Since the second and third fermion generations emerge dynamically from the reduction from 8-dim to  $4+4$  -dim Kaluza-Klein, they are also created/annihilated by the Primitive Idempotent E8 Higgs and are present in the fermion condensate. Since the Truth Quark is so much more massive than the other fermions,

**the E8 Higgs is effectively a Truth Quark condensate.**

When Triviality and Vacuum Stability are taken into account,

**the E8 Higgs and Truth Quark system has 3 mass states.**

Since it creates/annihilates Fermions,  
the (1+3)+(3+1) Associative part of the Cl(8) Primitive Idempotent  
is a Fermionic Condensate Higgs structure.  
The creation/annihilation operators have graded structure similar to part of a  
Heisenberg algebra

$$64 + 0 + 64$$

Since it creates/annihilates the 8-dimensional SpaceTime  
represented by the Cartan Subalgebra of the E8 Lie Algebra,  
the 8 = 4+4 Co-Associative part of the Cl(8) Primitive Idempotent  
is a Bosonic Condensate Spacetime structure.  
The creation/annihilation operators correspond to position-momentum related by  
Fourier Transform and to an 8x8 = 64-dimensional U(8)

E8 has two D4 Lie subalgebras D4 and D4\* related by Fourier Transform:  
28-dimensional D4 acting on M4 4-dim Physical SpaceTime and containing  
a Spin(2,4) subalgebra for Conformal MacDowell-Mansouri Gravity;  
and  
28-dimensional D4\* acting on CP2 Internal Symmetry Space and containing  
a U(4) subalgebra for the Batakis Standard Model gauge groups.

Taken together, the D4 and U(8) and D4\* have graded structure

$$28 + 64 + 28$$

that breaks down into a semi-simple 63-dimensional SU(8)

$$63$$

and a Heisenberg Algebra

$$28 + 1 + 28$$

When the Fermionic 64 + 0 + 64 is added, the Heisenberg Algebra becomes

$$92 + 1 + 92$$

and the total 92 + U(8) + 92 is seen to be the contraction of E8 into the  
semidirect product of semisimple SU(8) and Heisenberg Algebra 92 + U(1) + 92

Robert Hermann in “Lie Groups for Physicists” (Benjamin 1966) said:  
 “... Let  $G$  be a Lie group ... imbed  $G$  into the associative algebra  $U(G)$  ... the universal ... enveloping algebra ...  
 the “polynomials” of the .. basis [elements] of  $G$  ... form a basis for  $U(G)$  ...  
 the center of  $U(G)$  ...[is]... the Casimir operators of  $G$  ...[whose]... number ...[is]...  
 equal to ... the dimension of its Cartan subalgebras ...  
 every polynomial ... invariant under  $\text{Ad}G$  ... arise[s] ... from a Casimir operator ...  
 when  $G$  is semisimple,  $\text{Ad}G$  acting on  $G$  admits an invariant polynomial of degree  
 2 ... the Killing form ... This is the simplest such Casimir operator

...  
 there is a group-theoretical construction which in certain situations reduces to the  
 Fourier transform. To describe it, we need ... a Lie group  $G$ , two subgroups  $L$  and  
 $H$  of  $G$ , and linear representations ... of  $L$  and  $H$  ... on a vector space  $U$ , which  
 determines vector bundles  $E$  and  $E'$  over  $G/L$  and  $G/H$ . ...  
 A cross section  $\Psi$  of ...  $E'$  over  $G/H$  is an eigenvector of each Casimir operator of  
 $U(G)$  .... its transform  $\Psi^*$ , considered as a function on  $G/K$ , is also an  
 eigenfunction of each Casimir operator of  $U(G)$ . ...”.

Rutwig Campoamor-Stursberg in “Contractions of Exceptional Lie Algebras and  
 SemiDirect Products” (Acta Physica Polonica B 41 (2010) 53-77) said:  
 “... it is of interest to analyze whether ... semidirect products ... of semisimple and  
 Heisenberg Lie algebras ... appear as contractions of semisimple Lie algebras ...  
 Let  $s$  be a ... semisimple Lie algebra. For the indecomposable semidirect product  
 $\mathfrak{g} = s + \mathfrak{h}_N$  the number of Casimir operators is given by  $N(\mathfrak{g}) = \text{rank}(s) + 1$   
 ... In some sense, the Levi subalgebra  $s$  determines these Casimir invariants,  
 to which the central charge (the generator of the centre of the Heisenberg algebra)  
 is added. ... the quadratic Casimir operator will always contract onto the square of  
 the centre generator of the Heisenberg algebra ...  
 ... We have classified all contractions of complex simple exceptional Lie algebras  
 onto semidirect products ...  $s + \mathfrak{h}_N$  ... of semisimple and Heisenberg algebras.  
 An analogous procedure holds for the real forms of the exceptional algebras ...  
 Contractions of  $E_8$  ...  $E_8$  contains  $D_8$  contains  $A_7$  ... [ and for  $E_8$  ]...  $N = 92$   
 ... This reduction gives rise to the contraction ... [  $E_8$  to  $A_7 + \mathfrak{h}_{92}$  ]...  
 $E_8$  ... has primitive Casimir operators ... of degrees ... [ 2,8,12,14,18,20,24,30 ]...  
 $D_8$  ... has primitive Casimir operators ... of degrees ... [ 2,4,6,8,10,12,14,8 ]...  
 $A_7$  ... has primitive Casimir operators ... of degrees ... [ 2,3,4,5,6,7,8 ]...”.

The E8 primitive Casimirs 2, 8, 12, 14, 18, 20, 24, 30 contract as follows:

2 to the center U(1) of H92.

8, 12, 14 to the 8, 12, 14 of D8 and to the  $4=8/2$ ,  $6=12/2$ ,  $7=14/2$  of A7

18, 20, 24, 30 to the  $4=18-14$ ,  $6=20-14$ ,  $10=24-14$ ,  $8=(1/2)(30-14)$  of D8  
and to the  $2=4/2$ ,  $3=6/2$ ,  $5=10/2$ , 8 of A7

The 2, 8, 12, 14 of E8 are dual to the 30, 24, 20, 18 of E8 such that

$$2+30 = 8+24 = 12+20 = 14+18 = 32.$$

The E8 primitive Casimirs correspond to the Cartan subalgebras of E8 and of D8  
and also to 8-dim Spacetime and 4+4-dim Batakis Kaluza-Klein M4 x CP2

**The 2, 8, 12, 14 Casimirs of E8 correspond to  
the (1+3)-dim M4 Batakis Physical Spacetime**

**The 18, 20, 24, 30 Casimirs of E8 correspond to  
the 4-dim CP2 Batakis Internal Symmetry Space**

Weyl Symmetric Polynomial Degrees and Topological Types:

E8:

degrees - 2, 8, 12, 14, 18, 20, 24, 30

note that 1, 7, 11, 13, 17, 19, 23, and 29 are all relatively prime to 30

type - 3, 15, 23, 27, 35, 39, 47, 59; center =  $Z_1 = 1 =$  trivial

D8 Spin(16):

degrees - 2, 4, 6, 8, 10, 12, 14, 8

type - 3, 7, 11, 15, 19, 23, 27, 15; center =  $Z_2 + Z_2$

A7 SU(8):

degrees - 2, 3, 4, 5, 6, 7, 8

type - 3, 5, 7, 9, 11, 13, 15; center =  $Z_8$

Luis J. Boya has written a beautiful paper “Problems in Lie Group Theory” math-ph/0212067 and here are a few of the interesting things he says:

“... Given a Lie group in a series  $G(n)$  ... how is the group  $G(n+1)$  constructed?

For the **orthogonal series (Bn and Dn)** ... given  $O(n)$  acting on itself, that is, the adjoint (adj) representation, and the vector representation,  $n$ , ...

**Adj  $O(n)$  + Vect  $O(n)$   $\rightarrow$  Adj  $O(n+1)$  ...**

For the unitary series  $SU(n)$  ... **Adj  $SU(n)$  + Id +  $n$  +  $n^*$  = Adj  $SU(n+1)$  ...**

For the symplectic series

**Sp( $n$ ) =  $C_n$  ... Adj Sp( $n$ ) + Adj Sp(1) + 2( $n$  +  $n^*$ ) = Adj Sp( $n+1$ ) ...**

For  **$G_2$**  ... **Adj  $SU(3)$  +  $n$  +  $n^*$   $\rightarrow$   $G_2$  ...** [ in addition, I conjecture the existence of an alternate construction: **Adj  $O(4)$  + Vect  $O(4)$  + Spin  $O(4)$  =  $G_2$  ,** where Spin  $O(4)$  is its Spin representation, a notation that I will continue to use in the rest of this quotation instead of the notation Spin(4) that Boya uses, because I want to reserve the notation Spin(4) for the covering group of  $SO(4)$ . Note that Spin  $O(n)$  for even  $n$  is reducible to two copies of mirror image half-spinor representations half-Spin  $O(n)$  ]...

For the **exceptional groups, the F4 & E series** ...

- **Adj  $SO(9)$  + Spin  $O(9)$   $\rightarrow$  Adj  $F_4$  (36+16=52)**
- **Adj  $SO(10)$  + Spin  $O(10)$  + Id  $\rightarrow$  Adj  $E_6$  (45+32+1=78)**
- **Adj  $SO(12)$  + Spin  $O(12)$  + Sp(1)  $\rightarrow$  Adj  $E_7$  (66+64+3=133)**
- **Adj  $SO(16)$  + [half-]Spin  $O(16)$   $\rightarrow$  Adj  $E_8$  ([120+128=248])**

Notice that 8+1 , 8+2 , 8+4 , and 8+8 appear. In this sense the octonions appear as a "second coming " of the reals, completed with the spin, not the vector irrep. ...

This confirms that the  $F_4$   $E_6$ -7-8 corresponds to

the octo, octo-complex, octo-quater and octo-octo birings, as the Freudenthal Magic Square confirms. ...

Another ... question ... is the geometry associated to the exceptional groups ...

Are we happy with  $G_2$  as the automorphism group of the octonions,  $F_4$  as the isometry of the [octonion] projective plane,  $E_6$  (in a noncompact form) as the collineations of the same, and  $E_7$  resp.  $E_8$  as examples of symplectic resp. metasymplectic geometries? ... one would like to understand the exceptional groups ... as automorphism groups of some natural geometric objects. ...

The gross topology of Lie groups is well-known. The non-compact case reduces to compact times an euclidean space (Malcev-Iwasawa). The compact case is reduced to a finite factor, a Torus, and a semisimple compact Lie group.

H. Hopf determined in 1941 that the real homology of simple compact Lie groups is that of a product of odd spheres ...

The exponents of a Lie group are the numbers  $i$  such that  $S(2i+1)$  is an allowed sphere ...

neither the U-series nor the Sp-series have torsion.

The exponents ... for  $U(n)$  ... are  $0, 1, \dots, n-1$  ... and jump by two in  $Sp(n)$ .

But for the orthogonal series one has to consider some Stiefel manifolds instead of spheres, which have the same real homology ...

It ... introduces (preciesely) 2-torsion:

in fact,  $Spin(n)$ ,  $n \geq 7$  and  $SO(n)$ ,  $n \geq 3$ , have 2-torsion.

The low cases  $Spin(3,4,5,6)$  coincide

with  $Sp(1)$ ,  $Sp(1) \times Sp(1)$ ,  $Sp(2)$  and  $SU(4)$ , and have no torsion.

For ...  $G_2$  ...  $SU(2) \rightarrow G_2 \rightarrow M_{11}$  ... where  $M_{11}$  is again a Steifel manifold, with real homology like  $S_{11}$ , but with 2-torsion ...

For  $F_4$  we do not get the sphere structure from any irrep, and in fact  $F_4$  has 2- and 3-torsion. ...

2- and 3-torsion appears in ...  $E_6$  and  $E_7$  ...

$E_8$  has 2-, 3- and 5-torsion ...

The Coxeter number of (dim - rank) of  $E_8$  is  $30 = 2 \times 3 \times 5$ ,

in fact a mnemonic for the exponents of  $E_8$  is:

they are the coprimes up to 30, namely  $(1,7,11,13,17,19,23,29)$  ...

The first perfect numbers are 6, 28, and 492,

associated to the primes 2, 3 and 5 (... Mersenne numbers ...) ...

$496 = \dim O(32) = \dim E(8) \times E(8)$ . Why the square?

It also happens in  $O(4)$ ,  $\dim = 6$  (prime 2), as  $O(4)$  ...[is like]...  $O(3) \times O(3)$ ; even  $O(8)$  [ $\dim = 28$ ] (prime 3) is like  $S_7 \times S_7 \times G_2$  ...

The sphere structure of compact simple Lie groups has a curious "capicua" ... Catalan word ( cap i cua 0 = head and tail ) ... form: the exponents are symmetric from each end; for example ...

exponents of E6: 1,4,5,7,8,11. Differences: 3,1,2,1,3

exponents of E7: 1,5,7,9,11,13,17. Differences: 4,2,2,2,2,4 ...

exponents of E8 ... 1,7,11,13,17,19,23,29 ... [ Differences 6,4,2,4,2,4,6 ]...

The real homology algebra of a simple Lie group is a Grassmann algebra, as it is generated by odd (i.e., anticommutative) elements. However, from them we can get, in the enveloping algebra, multilinear symmetric forms, one for each generator; ... in physics they are called Casimir invariants, in mathematics the invariants of the Weyl group ...".

Martin Cederwall and Jakob Palmkvist, in "The octic E8 invariant" hep-th/0702024, say:

"... The largest of the finite-dimensional exceptional Lie groups, E8, with Lie algebra e8, is an interesting object ... its root lattice is the unique even self-dual lattice in eight dimensions (in euclidean space, even self-dual lattices only exist in dimension 8n). ... Because of self-duality, there is only one conjugacy class of representations, the weight lattice equals the root lattice, and there is no "fundamental" representation smaller than the adjoint. ...

Anything resembling a tensor formalism is completely lacking. A basic ingredient in a tensor calculus is a set of invariant tensors, or "Clebsch-Gordan coefficients". The only invariant tensors that are known explicitly for E8 are the Killing metric and the structure constants ...

The goal of this paper is to take a first step towards a tensor formalism for E8 by explicitly constructing an invariant tensor with eight symmetric adjoint indices. ...

On the mathematical side, the disturbing absence of a concrete expression for this tensor is unique among the finite-dimensional Lie groups. Even for the smaller exceptional algebras g2, f4, e6 and e7, all invariant tensors are accessible in explicit forms, due to the existence of "fundamental" representations smaller than the adjoint and to the connections with octonions and Jordan algebras. ...

The orders of Casimir invariants are known for all finite-dimensional semi-simple Lie algebras. They are polynomials in  $U(\mathfrak{g})$ , the universal enveloping algebra of  $\mathfrak{g}$ , of the form  $t(A_1 \dots A_k) T^{(A_1 \dots A_k)}$ , where  $t$  is a symmetric invariant tensor and  $T$  are generators of the algebra, and they generate the center  $U(\mathfrak{g})^{\mathfrak{g}}$  of  $U(\mathfrak{g})$ .

The Harish-Chandra homomorphism is the restriction of an element in  $U(\mathfrak{g})^{\mathfrak{g}}$  to a polynomial in the Cartan subalgebra  $\mathfrak{h}$ , which will be invariant under the Weyl group  $W(\mathfrak{g})$  of  $\mathfrak{g}$ .

Due to the fact that the Harish-Chandra homomorphism is an isomorphism from  $U(\mathfrak{g})^{\mathfrak{g}}$  to  $U(\mathfrak{h})^{W(\mathfrak{g})}$  one may equivalently consider finding a basis of generators for the latter, a much easier problem. The orders of the invariants follow more or less directly from a diagonalisation of the Coxeter element, the product of the simple Weyl reflections ...

In the case of  $e_8$ , the center  $U(e_8)^{e_8}$  of the universal enveloping subalgebra is generated by elements of orders 2, 8, 12, 14, 18, 20, 24 and 30. The quadratic and octic invariants correspond to primitive invariant tensors in terms of which the higher ones should be expressible. ... the explicit form of the octic invariant is previously not known ...

$E_8$  has a number of maximal subgroups, but one of them,  $Spin(16)/Z_2$ , is natural for several reasons. Considering calculational complexity, this is the subgroup that leads to the smallest number of terms in the Ansatz.

Considering the connection to the Harish-Chandra homomorphism,  $K = Spin(16)/Z_2$  is the maximal compact subgroup of the split form  $G = E_8(8)$ .

The Weyl group is a discrete subgroup of  $K$ , and the Cartan subalgebra  $\mathfrak{h}$  lies entirely in the coset directions  $\mathfrak{g}/\mathfrak{k}$  ...

We thus consider the decomposition of the adjoint representation of  $E_8$  into representations of the maximal subgroup  $Spin(16)/Z_2$ .

The adjoint decomposes into the adjoint 120 and a chiral spinor 128. ...

Our convention for chirality is  $\text{GAMMA}_{(a_1 \dots a_{16})} \text{PHI} = + e_{(a_1 \dots a_{16})} \text{PHI}$  .

The  $e_8$  algebra becomes ( 2.1 )

$$\begin{aligned} [ T^{(ab)} , T^{(cd)} ] &= 2 \delta^{([a}_{(c} T^{(b)]}_{(d)}] , \\ [ T^{(ab)} , \text{PHI}^{(\alpha)} ] &= (1/4) ( \text{GAMMA}^{(ab)} \text{PHI} )^{(\alpha)} , \\ [ \text{PHI}^{(\alpha)} , \text{PHI}^{(\alpha)} ] &= (1/8) ( \text{GAMMA}_{(ab)} )^{(\alpha \beta)} T^{(ab)} , \end{aligned}$$

... The coefficients in the first and second commutators are related by the  $so(16)$  algebra. The normalisation of the last commutator is free, but is fixed by the choice for the quadratic invariant, which for the case above is

$$X_2 = (1/2) T_{(ab)} T^{(ab)} + \text{PHI}_{(\alpha)} \text{PHI}^{(\alpha)} .$$

Spinor and vector indices are raised and lowered with  $\delta$  .  
Equation (2.1) describes the compact real form,  $E_8(-248)$  .

By letting  $\text{PHI} \rightarrow i \text{PHI}$  one gets  $E_8(8)$ ,  
where the spinor generators are non-compact,  
which is the real form relevant as duality symmetry in three dimensions  
(other real forms contain a non-compact  $\text{Spin}(16)/\mathbb{Z}_2$  subgroup).

The Jacobi identities are satisfied thanks to the Fierz identity

$$(\text{GAMMA}_{(ab)}_{(\alpha \beta)} (\text{GAMMA}_{(ab)}_{(\alpha \beta)}) = 0 ,$$

which is satisfied for  $so(8)$  with chiral spinors,  $so(9)$ , and  $so(16)$  with chiral spinors  
( in the former cases the algebras are  $so(9)$ , due to triality, and  $f_4$  ).

The Harish-Chandra homomorphism tells us that the "heart" of the invariant lies in an octic Weyl-invariant of the Cartan subalgebra.

A first step may be to lift it to a unique  $\text{Spin}(16)/\mathbb{Z}_2$ -invariant in the spinor, corresponding to applying the isomorphism  $f_4 \rightarrow \mathbb{1}$  above.

It is gratifying to verify ... that there is indeed an octic invariant  
( other than  $(\text{PHI} \text{PHI})^4$  ), and that no such invariant exists at lower order. ...

Forming an element of an irreducible representation containing a number of spinors involves symmetrisations and subtraction of traces, which can be rather complicated. This becomes even more pronounced when we are dealing with transformation ... under the spinor generators, which will transform as spinors.

Then irreducibility also involves gamma-trace conditions. ... The transformation ... under the action of the spinorial generator is an  $so(16)$  spinor. The vanishing of this spinor is equivalent to  $e_8$  invariance. The spinorial generator acts similarly to a supersymmetry generator on a superfield ... The final result for the octic invariant is, up to an overall multiplicative constant:

$$\begin{aligned}
X_8 = & \frac{1}{3072} \varepsilon^{a_1 \dots a_{16}} T_{a_1 a_2} \dots T_{a_{15} a_{16}} \\
& - 30 \text{tr} T^8 + 14 \text{tr} T^6 \text{tr} T^2 + \frac{35}{4} (\text{tr} T^4)^2 - \frac{35}{8} \text{tr} T^4 (\text{tr} T^2)^2 + \frac{15}{64} (\text{tr} T^2)^4 \\
& + [2 \text{tr} T^6 - \text{tr} T^4 \text{tr} T^2 + \frac{1}{8} (\text{tr} T^2)^3] (\phi \phi) \\
& + [(\frac{5}{4} \text{tr} T^4 - \frac{1}{2} (\text{tr} T^2)^2) T^{ab} T^{cd} + \frac{27}{4} \text{tr} T^2 T^{ab} (T^3)^{cd} \\
& \quad - 15 T^{ab} (T^5)^{cd} - 15 (T^3)^{ab} (T^3)^{cd}] (\phi \Gamma_{abcd} \phi) \\
& + [\frac{1}{16} \text{tr} T^2 T^{ab} T^{cd} T^{ef} T^{gh} - \frac{5}{8} T^{ab} T^{cd} T^{ef} (T^3)^{gh}] (\phi \Gamma_{abcdefgh} \phi) \\
& - \frac{1}{192} T^{ab} T^{cd} T^{ef} T^{gh} T^{ij} T^{kl} (\phi \Gamma_{abcdefghijkl} \phi) \\
& + [7 \text{tr} T^4 - \frac{31}{8} (\text{tr} T^2)^2] (\phi \phi)^2 \\
& - \frac{3}{64} T^{ab} T^{cd} T^{ef} T^{gh} (\phi \phi) (\phi \Gamma_{abcdefgh} \phi) \\
& + [\frac{5}{64} T^{ab} T^{cd} T^{ef} T^{gh} - \frac{15}{16} T^{ab} T^{ce} T^{df} T^{gh} \\
& \quad + \frac{5}{8} T^{ae} T^{bf} T^{cg} T^{dh}] (\phi \Gamma_{abcd} \phi) (\phi \Gamma_{efgh} \phi) \\
& + [\frac{3}{2} (T^3)^{ab} T^{cd} - \frac{1}{8} \text{tr} T^2 T^{ab} T^{cd}] (\phi \phi) (\phi \Gamma_{abcd} \phi) \\
& + [\frac{15}{16} (T^3)^{ab} T^{cd} - \frac{3}{16} \text{tr} T^2 T^{ab} T^{cd} + \frac{5}{4} (T^2)^{ac} (T^2)^{bd}] (\phi \Gamma_{ab}{}^{ij} \phi) (\phi \Gamma_{cdij} \phi) \\
& + \frac{15}{8} T^{ab} T^{cd} (T^2)^{ef} (\phi \Gamma_{abc}{}^i \phi) (\phi \Gamma_{cdfi} \phi) \\
& + \frac{1}{2} \text{tr} T^2 (\phi \phi)^3 + \frac{55}{32} T^{ab} T^{cd} (\phi \phi)^2 (\phi \Gamma_{abcd} \phi) \\
& + \frac{1}{8} T^{ab} T^{cd} (\phi \phi) (\phi \Gamma_{ab}{}^{ij} \phi) (\phi \Gamma_{cdij} \phi) \\
& + [-\frac{1}{384} T^{ab} T^{cd} + \frac{7}{192} T^{ac} T^{bd}] (\phi \Gamma_{ab}{}^{ij} \phi) (\phi \Gamma_{cd}{}^{kl} \phi) (\phi \Gamma_{ijkl} \phi) \\
& - \frac{57}{32} (\phi \phi)^4 + \frac{1}{12288} (\phi \Gamma_{ab}{}^{cd} \phi) (\phi \Gamma_{cd}{}^{ef} \phi) (\phi \Gamma_{ef}{}^{gh} \phi) (\phi \Gamma_{gh}{}^{ab} \phi) \\
& + \beta [-\frac{1}{2} \text{tr} T^2 + (\phi \phi)]^4 .
\end{aligned} \tag{2.3}$$

Here,  $\beta$  is an arbitrary constant multiplying the fourth power of the quadratic invariant. The trace vanishes for  $\beta = \frac{9}{127}$  (that such a value exists at all is non-trivial and provides a further check on the coefficients). The occurrence of the prime 127 is not incidental; taking the trace of  $\delta^{(AB} \delta^{CD} \delta^{EF} \delta^{GH)}$  gives  $\delta_{GH} \delta^{(AB} \delta^{CD} \delta^{EF} \delta^{GH)} = (\frac{1}{7} \cdot 248 + \frac{6}{7}) \delta^{(AB} \delta^{CD} \delta^{EF)} = \frac{2 \cdot 127}{7} \delta^{(AB} \delta^{CD} \delta^{EF)}$ . The actual technique we use for calculating the trace is not to extract the eight-index tensor, but to act on the invariant with  $\frac{1}{2} \frac{\partial}{\partial T^{ab}} \frac{\partial}{\partial T^{ac}} + \frac{\partial}{\partial \phi_a} \frac{\partial}{\partial \phi^a}$ . We remind that eq. (2.3) gives the octic invariant for the compact form  $E_{8(-248)}$ . The corresponding expression for the split form  $E_{8(8)}$  is obtained by a sign change of the terms containing  $\phi^{4k+2}$ .
